```
while( fgets( riga, MAXRIGA, f ) != NULL )
```

Greedy Algorithms

Greedy Algorithms

Stefano Quer

Dipartimento di Automatica e Informatica

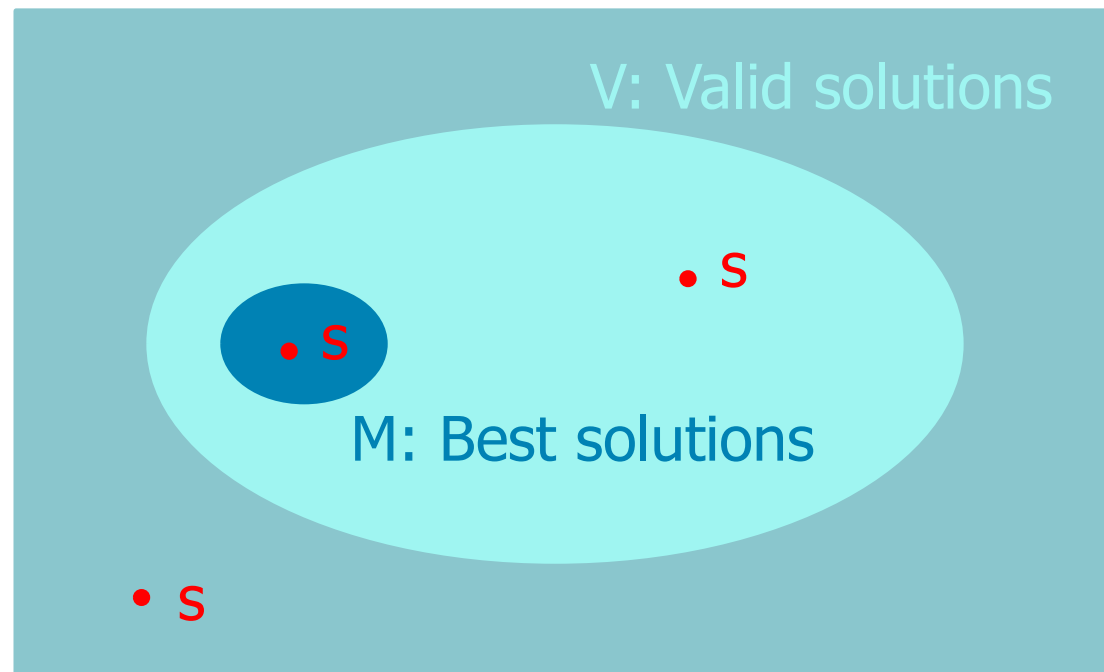

Politecnico di Torino

Optimization Algorithms

- ❖ Algorithms for optimization problems typically look for optimal solutions and
 - Go through a sequence of steps
 - Make a set of choices at each step to reach the desired target

S: All Solutions

V: Valid solutions

Greedy Algorithms

❖ Many optimization problems

- Have very expensive solutions adopting brute-force recursion or dynamic programming
- Sometimes, they may be easily solved with simpler and more efficient algorithms
 - Instead of making exhaustive choices, it is possible to make the choice that looks best at the moment hoping that locally optimal choices will lead to a globally optimal solution
 - This is the strategy followed by **greedy algorithms**
 - Greedy algorithms may be quite powerful and it may work well for a wide range of problems

Greedy Algorithms

❖ Greedy algorithms

- Seek globally optimal solutions by making locally optimal choices
 - Decisions are considered locally optimal based on an appetibility (or cost) function
- Never reconsider previously taken decisions
 - They never perform backtracking
- For the above reason greedy algorithms
 - Are very simple and efficient
 - Have limited process time

Greedy Algorithms

❖ The cost function may be

➤ Selected a priori and never changed thereafter

- We start from the empty solution
- We sort choices according to the cost function
- We make choices in descending appetibility order, adding, if possible, the result to the partial solution

➤ Modifiable during the process

- The process proceeds as before, but choices are stored in a priority queue
- The appetibility value (cost function) represents the priority used to select the choices and it varies from step to step

Greedy Algorithms

❖ The solution is not always optimal, but for many problems it is

➤ Optimal solution

- Best possible solution

➤ Locally optimal solution

- Best possible solution within a contiguous domain

Algorithms

- ❖ In this unit, we analyze two algorithms in which greedy choices lead to optimal solutions
 - The Activity Selection problem
 - The Huffman code to perform data compression
- ❖ In the graph units we are going to see a few other greedy algorithms
 - Prim's and Kruskal's Minimum-Spanning-Tree
 - Dijkstra's Single-Source-Shortest-Path

Activity Selection Problem

- ❖ In the activity selection problem, we
 - Have to schedule several competing activities that requires exclusive usage of a common resource
 - Each activity has a start and an finish time
 - The goal is to select a maximum-size subset of mutually compatible activities
 - Two activities are compatible if they do not overlap in time as they must use the **same** resource (e.g., a classroom, a specific device, etc.)

Activity Selection Problem

❖ To build an optimal solution, we define

➤ **Input**

- Set of n activities with start time (s) and finish (f) time $[s, f)$ (or $[s, f[$)

➤ **Output**

- Sub-set with the maximum number of compatible activities $[s_i, f_i)$

➤ **Constraints**

- No selected activity $[s_i, f_i)$ overlaps with another one $[s_j, f_j)$, that is, $s_j \geq f_i$ or $s_i \geq f_j$

Activity Selection Problem

➤ Greedy iterative approach

- Set A is the initial set of activities
- Set S is the final sub-set of activities
- Sort the activities in A by increasing finish time
- Initialize S to the empty set \emptyset
- While the set of activity A is not empty
 - Select the earliest activity s in A to finish
 - If s is compatible with every activity in S , add s to S
- Return the set A

Example

Initial activity
(sorted by increasing finish time)

Selected activity

| k | s_k | f_k |
|-----|-------|-------|
| 1 | 1 | 4 |
| 2 | 3 | 5 |
| 3 | 0 | 6 |
| 4 | 5 | 7 |
| 5 | 3 | 9 |
| 6 | 5 | 9 |
| 7 | 6 | 10 |
| 8 | 8 | 11 |
| 9 | 8 | 12 |
| 10 | 2 | 14 |
| 11 | 12 | 16 |

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16

Solution

Initial activity
(sorted by increasing finish time)

Selected activity
1

| k | s_k | f_k |
|-----|-------|-------|
| 1 | 1 | 4 |
| 2 | 3 | 5 |
| 3 | 0 | 6 |
| 4 | 5 | 7 |
| 5 | 3 | 9 |
| 6 | 5 | 9 |
| 7 | 6 | 10 |
| 8 | 8 | 11 |
| 9 | 8 | 12 |
| 10 | 2 | 14 |
| 11 | 12 | 16 |

Solution

Initial activity
(sorted by increasing finish time)

Selected activity
1, 4, 8, 11

| k | s_k | f_k |
|-----|-------|-------|
| 1 | 1 | 4 |
| 2 | 3 | 5 |
| 3 | 0 | 6 |
| 4 | 5 | 7 |
| 5 | 3 | 9 |
| 6 | 5 | 9 |
| 7 | 6 | 10 |
| 8 | 8 | 11 |
| 9 | 8 | 12 |
| 10 | 2 | 14 |
| 11 | 12 | 16 |

Implementation

The iterative C implementation

```
typedef struct activity {
    char name[MAX];
    int start, stop;
    int selected;
} activity_t;
```

Data-base definition

...

```
int cmp (const void *p1, const void *p2);
```

Compare Function

...

```
acts = load(argv[1], &n); load activity array
qsort ((void *)acts, n, sizeof(activity_t), cmp); asc sort by stop
choose (acts, n);
display (acts, n);
```

C Standard Library

...

Implementation

```
int cmp (const void *p1, const void *p2) {  
    activity_t *a1 = (activity_t *)p1;  
    activity_t *a2 = (activity_t *)p2;  
    return a1->stop - a2->stop;  
}
```

```
void choose (activity_t *acts, int n) {  
    int i, stop;
```

```
    acts[0].selected = 1;  
    stop = acts[0].stop;  
    for (i=1; i<n; i++) {  
        if (acts[i].start >= stop) {  
            acts[i].selected = 1;  
            stop = acts[i].stop;  
        }  
    }  
}
```

we check from the beginning since we already sorted

```
}
```

prototype quicksort: `qsort(void *, int, int, int *f(void *, void *))`

Huffman Codes

- ❖ Huffman in 1950 invented a greedy algorithm that construct an optimal prefix code give a set of symbols S
- ❖ Codeword
 - String of bits associated to a symbol $s \in S$
- ❖ Encoding
 - From symbol to codeword
- ❖ Decoding
 - From codeword to symbol

Huffman Codes

❖ It is possible to have fixed-length and variable-length codes

➤ Fixed-length codes

- Codewords with $n = \lceil \log_2(|S|) \rceil$ bits
- Pro: easy to decode
- Use: symbol occurring with the same frequency

➤ Variable-length codes

- Con: difficult to decode
- Pro: memory savings
- Use: symbols occurring with different frequencies
- Example
 - Morse alphabet (with pauses between words)

The Morse Code

International Morse Code

1. The length of a dot is one unit.
2. A dash is three units.
3. The space between parts of the same letter is one unit.
4. The space between letters is three units.
5. The space between words is seven units.

Example

❖ Give a file with only 6 different characters but storing 100.000 characters overall

❖ We can encode the file using

3 bits → 8 different values > 6

➤ A fixed-length code with 3 bits per code, storing

$$3 \cdot 100000 = 300000 \text{ bits}$$

➤ A variable-length code with 1-4 bits per code, storing

$$(0.45 \cdot 1 + 0.13 \cdot 3 + 0.12 \cdot 3 + 0.16 \cdot 3 + 0.09 \cdot 4 + 0.05 \cdot 4) \cdot 1000 = 224000 \text{ bits}$$

| | a | b | c | d | e | f |
|-----------------|----------|----------|----------|----------|----------|----------|
| Frequency | 45% | 13% | 12% | 16% | 9% | 5% |
| Fixed-length | 000 | 001 | 010 | 011 | 100 | 101 |
| Variable-length | 0 | 101 | 100 | 111 | 1101 | 1100 |

Prefix-codes

- ❖ We consider codes in which no codeword is also a prefix of another valid codeword
- ❖ These codes are called **prefix-codes**
 - Prefix-codes can always achieve the optimal data compression among any character code
 - We suffer no loss of generality
- ❖ For prefix-codes
 - Encoding
 - Juxtaposition of strings
 - Decoding
 - Path on a binary tree

Example

- ❖ The correspondence symbols-codes can be stored in a tree

$a = 0$
 $b = 101$
 $c = 100$
 $d = 111$
 $e = 1101$
 $f = 1100$

Example: Encoding

❖ Encoding

➤ Is the evaluation of the codes starting from the symbols

abfaac → 0101110000100

Example: Decoding

❖ Decoding

➤ Is the evaluation of the symbols starting from the codes

0101110000100 → *abfaac*

Building the tree

- ❖ To implement the previous algorithm, we must create the correspondence tree
- ❖ Data structure
 - Priority queue used to store tree nodes with their frequency
 - Each tree node represent an initial code or an aggregate
 - The frequency of the code or the aggregate is the priority

Building the tree

❖ Algorithm

➤ Initially

- Each symbol is a tree leaf

➤ Intermediate step

- Extract the 2 symbols (or aggregates) with minimum frequency
- Build the binary tree (aggregate of symbols)
 - Each node is a symbol or aggregate
 - Its frequency is the sum of the frequencies
- Insert the new aggregate into priority queue

➤ Termination

- Empty queue

Example

❖ Given the following frequencies

letter: relative frequency

$f:5$ $e:9$ $c:12$ $b:13$ $d:16$ $a:45$

- Find an optimal Huffman code for all symbols in the set using a greedy algorithm
- Indicate the code that must be used to represent all symbols in the set

❖ Note

- In all following steps, we store symbols and aggregates in a **sorted array**
- Anyway, a sorted array is **far less efficient** than a priority queue in practice

Solution: Step 1

Priory Queue (fully sorted)

f:5 e:9 c:12 b:13 d:16 a:45

Extract

Build the tree of the aggregate

Insert the aggregate back into the priority queue

Solution: Step 2

Extract

Build the tree of the aggregate

Insert the aggregate back into the priority queue

Solution: Step 3

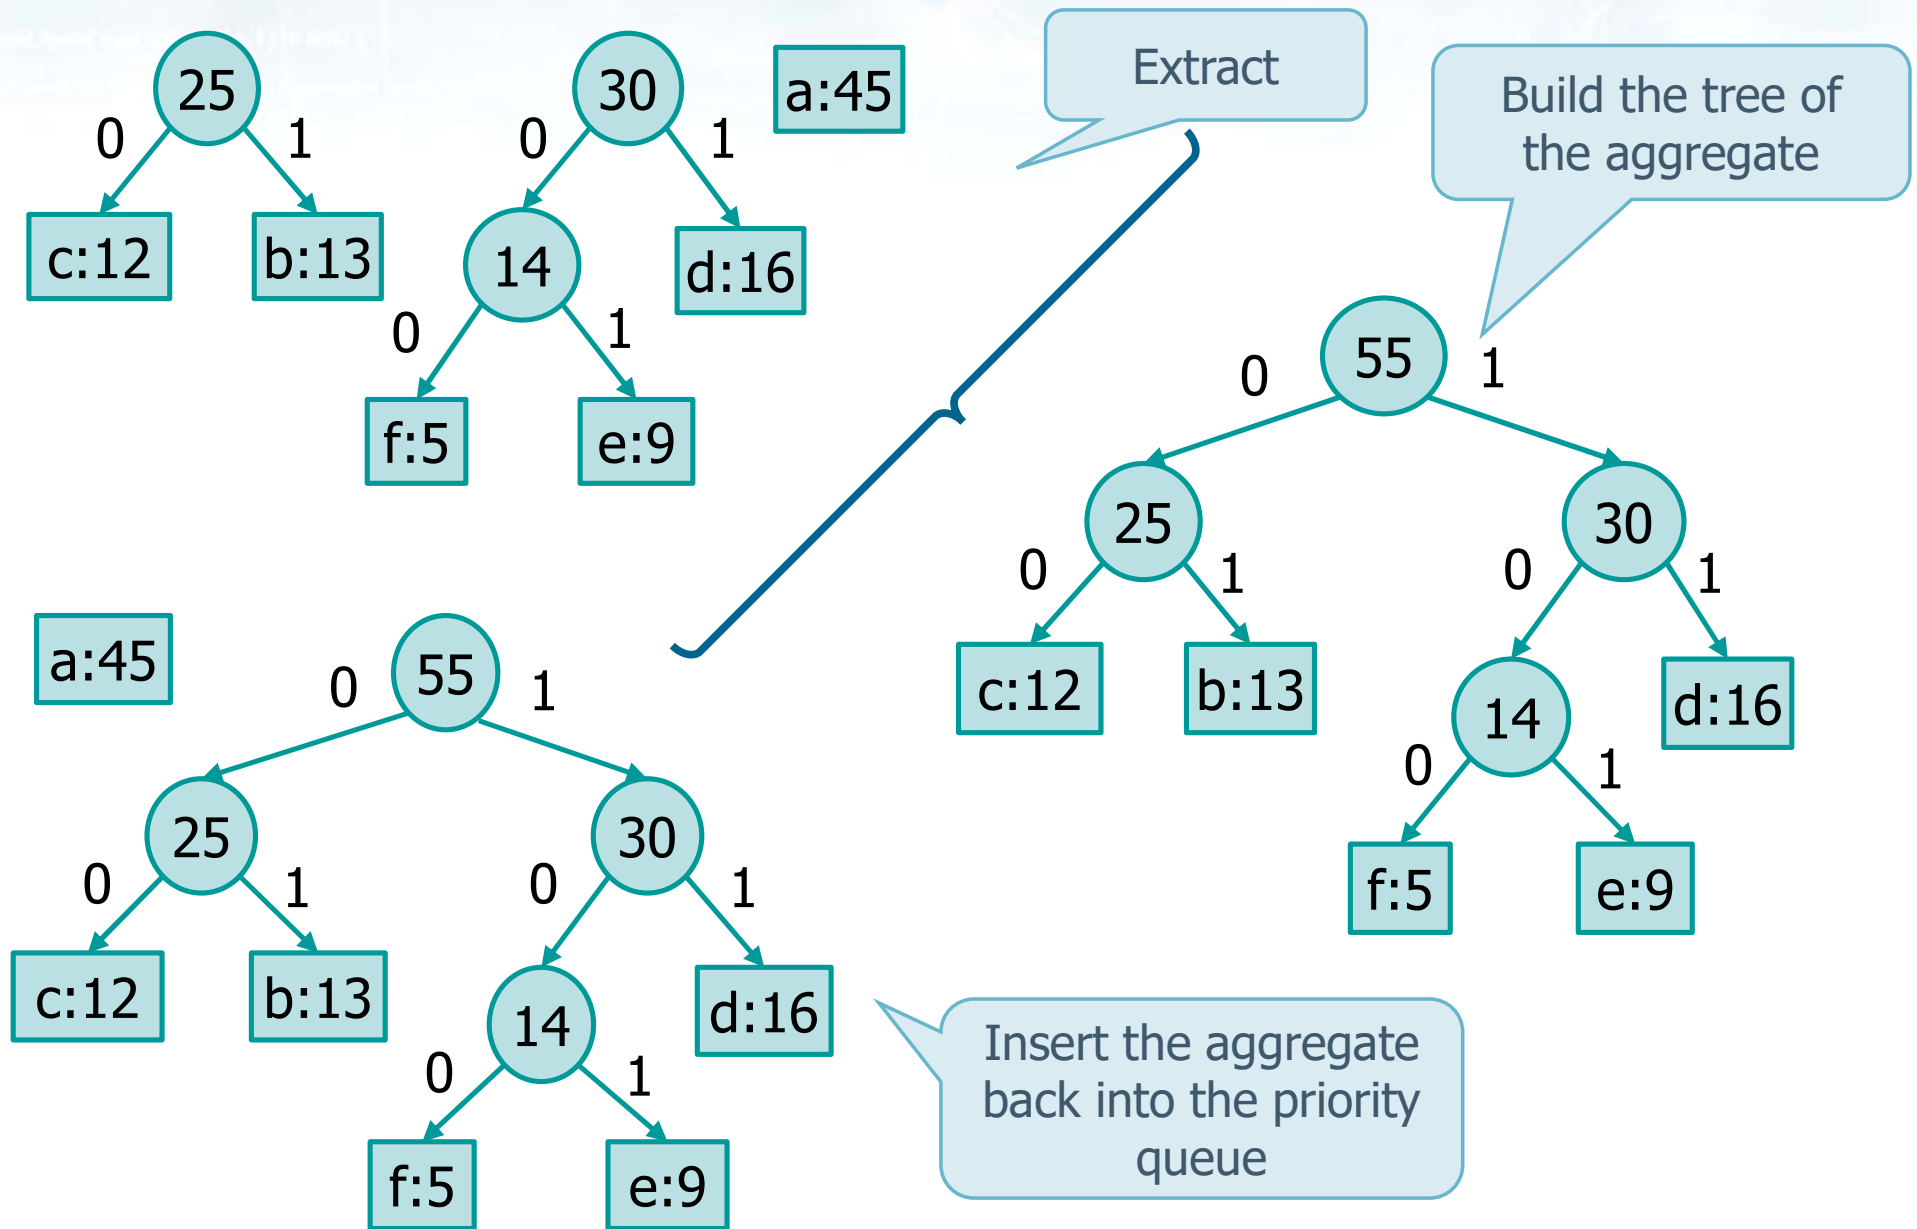

Extract

Build the tree of the aggregate

Insert the aggregate back into the priority queue

Solution: Step 4

Solution: Step 5

Extract

Build the tree of the aggregate

Implementation

Functions **pq_*** are in the priority queue (PQ) library

```
PQ *pq;  
  
pq = pq_init (maxN, item_compare);  
  
for (i=0; i<maxN; i++) {  
    printf ("Enter letter & frequency: ");  
    scanf ("%s %d", &letter, &freq);  
  
    tmp = item_new (letter, freq);  
  
    pq_insert (pq, tmp);  
}
```

Init Heap / Code

Functions **item_*** are in the data-item library

Implementation

`pq_extract_max`: Maximum
priority minimum frequency

Generate
code

```
while (pq_size(pq) > 1) {  
  
    l = pq_extract_max (pq);  
    r = pq_extract_max (pq);  
    tmp = item_new ('!', l->freq + r->freq);  
    tmp->left = l;  
    tmp->right = r;  
    pq_insert (pq, tmp);  
  
}  
  
root = pq_extract_max (pq);  
pq_display (root, code, 0);
```

Visit and print tree
(and codes)

Complexity

❖ When

- Heap is implemented as a binary tree
- Extract and insert operations manipulate a priority queues

the complexity of the algorithm is

$$T(n) = O(n \cdot \log_2 n)$$

Exercise

- ❖ Given the following set of activities, find the a maximum-size subset of mutually compatible activities

Exercise A

| Activity | s_i | f_i |
|----------------|-------|-------|
| P ₁ | 1 | 4 |
| P ₂ | 3 | 5 |
| P ₃ | 7 | 15 |
| P ₄ | 6 | 9 |
| P ₅ | 11 | 13 |
| P ₆ | 11 | 12 |
| P ₇ | 5 | 8 |
| P ₈ | 4 | 9 |

Exercise B

| Activity | s_i | f_i |
|-----------------|-------|-------|
| P ₁ | 7 | 8 |
| P ₂ | 21 | 23 |
| P ₃ | 20 | 24 |
| P ₄ | 4 | 5 |
| P ₅ | 15 | 17 |
| P ₆ | 0 | 3 |
| P ₇ | 6 | 7 |
| P ₈ | 27 | 31 |
| P ₉ | 8 | 12 |
| P ₁₀ | 26 | 32 |
| P ₁₁ | 3 | 8 |
| P ₁₂ | 29 | 31 |
| P ₁₃ | 9 | 11 |

Solution

❖ Selected activities

Solution A

| Activity | s_i | f_i |
|----------------|-------|-------|
| P ₁ | 1 | 4 |
| P ₇ | 5 | 8 |
| P ₆ | 11 | 12 |

Solution B

| Activity | s_i | f_i |
|-----------------|-------|-------|
| P ₆ | 0 | 3 |
| P ₄ | 4 | 5 |
| P ₇ | 6 | 7 |
| P ₁ | 7 | 9 |
| P ₁₃ | 9 | 11 |
| P ₅ | 15 | 17 |
| P ₂ | 21 | 23 |

Exercise

❖ Given the following frequencies

A: 13 B: 29 C: 35 D: 8 E: 20 F: 6 G: 17 H: 5

Exercise A

Exercise B

A: 6 B: 20 C: 14 D: 3 E: 35 F: 13 G: 24 H: 19 I: 12 J: 17

- Find an optimal Huffman code for all symbols in the set using a greedy algorithm
- Indicate the code that must be used to represent all symbols in the set

Solution A

A: 13 B: 29 C: 35 D: 8 E: 20 F: 6 G: 17 H: 5
