    fprintf(stderr, "ERRORE, serve un parametro con il nome del file\n");
    exit(1);
}
```

```
f = fopen(argv[1], "r");
if(f==NULL)
```

```
{
    fprintf(stderr, "ERRORE, impossibile aprire il file %s\n", argv[1]);
    exit(1);
}
```

```
while( fgets( riga, MAXRIGA, f ) != NULL )
```

# Dynamic Programming

## Dynamic Programming

Stefano Quer

Dipartimento di Automatica e Informatica

Politecnico di Torino

# Basics

## ❖ A divide-and-conquer algorithm

- Partition the problem into disjoint subproblems
- Solve the subproblems recursively
- Combine their solutions to solve the original problem
- When a problem shares sub-problems a divide-and-conquer algorithm does more work than necessary
  - It repeatedly solves the common sub-sub-problems over and over again

# Basics

## ❖ Dynamic programming

- Like the divide-and-conquer method, solves problems by combining the solutions to subproblems
- Applies when sub-problems overlap, i.e., when sub-problems share sub-sub-problems
  - Solves each sub-sub-problem just once
  - Saves its result in a table
  - Uses such a result every time it encounters the same sub-sub-problem, thus avoiding the work of recomputing the answer

# Basics

- ❖ Dynamic programming is typically applied to optimization problems
  - These problems can have many possible solutions
    - Each solution is characterized by a “fitness” value
    - We wish to find a solution with the optimal (minimum or maximum) value
  - We call such a solution **an** optimal solution to the problem, as opposed to **the** optimal solution, since there may be several solutions that achieve the optimal value

## Basics

- Thus, to develop a dynamic-programming algorithm, we need to
  - Characterize the structure of an optimal solution
  - Recursively define its value
  - Compute this value (typically in a bottom-up fashion) and construct an optimal solution from it

## ➤ Iterative and recursive definition

## ➤ Divide-and-conquer approach

[illegible]

The number of rabbit pairs form the Fibonacci sequence

# Fibonacci Numbers

```
long int fib (long int n) {
    if (n == 0 || n == 1)
        return (n);
    return (fib(n-2) + fib(n-1));
}
```

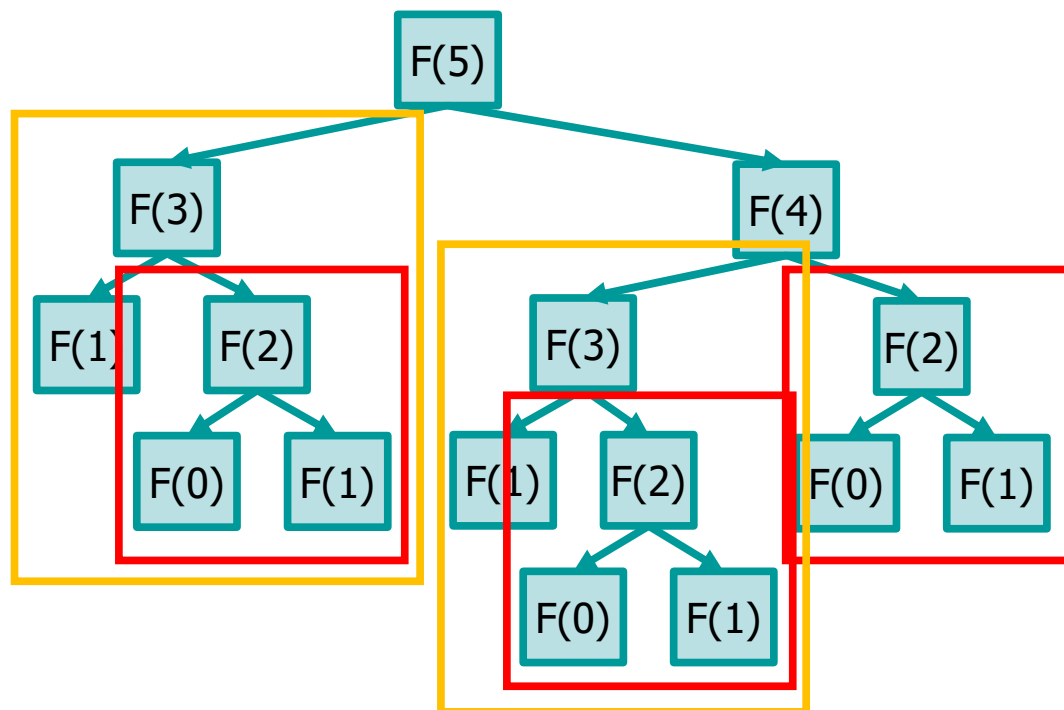

Sub-problems are not independent

Recomputations lead to inefficiency

# Fibonacci: Dynamic programming

```
long int fib (long int n) {
    if (n == 0 || n == 1)
        return (n);
    return (fib(n-2) + fib(n-1));
}
```

Dynamic Programming

# Fibonacci: Dynamic programming

- ❖ To get a more efficient solution, we must
  - Store solutions to subproblems as soon as they are found
  - Before solving a problem, check whether it has already been solved
  - Reuse existing partial solutions
  - In this way, we can improve the Fibonacci function from being  $O(2^n)$  to  $O(n)$

# Fibonacci: Dynamic programming

```
int main (void) {
    int *known, i, n;
    fprintf(stdout, "Input n: ");
    scanf("%d", &n);
    known = (int *) malloc ((n+1)*sizeof(int));
    if (known==NULL){
        fprintf (stderr, "Memory allocation error.\n");
        exit(EXIT_FAILURE);
    }
    for (i=0; i<=n; i++) {
        known[i] = -1;
    }
    fprintf(stdout, "Fibonacci %d-th term = %d\n",
        n, fib_dp(n, known));
    free(known);
    return EXIT_SUCCESS;
}
```

We define an array  
**known**

# Fibonacci: Dynamic programming

```
int fib_dp (int n, int *known) {  
    if (known[n] < 0) {  
        if (n==0 || n==1) {  
            known[n] = n;  
        } else {  
            known[n] = fib_dp (n-1, known) +  
                       fib_dp (n-2, known);  
        }  
    }  
  
    return known[n];  
}
```

We avoid all recomputations

We store partial results into array **known**

# Dynamic programming

- ❖ Dynamic programming uses additional memory to save computation time
  - Time-memory trade-off
  - Savings may be dramatic, i.e., exponential-time solution may be transformed into polynomial-time solutions
- ❖ There are usually two equivalent ways to implement a dynamic-programming approach

Memoization not  
memorization !

## Approach 1

### ❖ Top-down with memoization

- We write the standard recursive procedure
- We modify it to
  - Save the result of each subproblem (usually in an array or a hash table)
  - Check whether each problem has previously been solved
    - If so, we return the saved value, saving further computation at this level
    - If not, the procedure computes the value in the usual manner
- The recursive procedure has been memorized, i.e., it “remembers” what results it has computed previously

## Approach 2

### ❖ Bottom-up

- As any sub-problem depends only on “smaller” sub-problems
  - We sort the sub-problems by size
  - We solve them in size order, smallest first
    - We solve each subproblem only once
    - When we encounter it, we have already solved all of its prerequisite sub-problems and we have saved their solutions

## Matrix-chain multiplication

<https://www.youtube.com/watch?v=prx1psByp7U>

- ❖ Given a sequence (chain) of matrices  $M_i$  (with  $i \in [1, n]$ ) to be multiplied

$$M = M_1 \cdot M_2 \cdot M_3 \cdot \dots \cdot M_n$$

where matrix  $M_i$  has dimension  $r_i \cdot c_i$

- Fully parenthesize the product in a way that minimizes the number of scalar multiplications necessary to compute  $M$ 
  - That is, decide in which order compute the product (on a pair-by-pair basis)

## The standard algorithm

```
for (i=0; i<r1; i++) {
    for (j=0; j<c2; j++) {
        m[i][j] = 0;
        for (k=0; k<c1; k++) {
            m[i][j] += m1[i][k] * m2[k][j];
        }
    }
}
```

- ❖ How can we evaluate the product of  $n$  matrices?
  - We can use the **standard algorithm** for multiplying **pairs** of matrices

## The standard algorithm

```
for (i=0; i<r1; i++) {  
    for (j=0; j<c2; j++) {  
        m[i][j] = 0;  
        for (k=0; k<c1; k++) {  
            m[i][j] += m1[i][k] * m2[k][j];  
        }  
    }  
}
```

- Each matrix pair must be compatible, i.e., computing  $M = M_1 \cdot M_2$ 
  - Is feasible only if  $c_1 = r_2$  and  $M$  will have size  $(r \cdot c)$  such that  $r = r_1$  and  $c = c_2$
- Moreover, the time to compute  $M$  is dominated by the number of scalar multiplications
  - This number is equal to  $r_1 \cdot c_2 \cdot c_1$

**Example**

Please, remind that we know how to multiply two matrices

❖ Let us suppose we need to compute

Matrix size for  $M_1$ ,  $M_2$ , and  $M_3$

$$M = M_1 \cdot M_2 \cdot M_3$$

$(10 \cdot 100) \quad (100 \cdot 5) \quad (5 \cdot 50)$

Number of products

❖ We have two possible solutions

$$\begin{array}{ll} (M_1 \cdot M_2) \cdot M_3 & cost = r_1 \cdot c_2 \cdot c_1 + r_1 \cdot c_3 \cdot c_2 = 10 \cdot 5 \cdot 100 + 10 \cdot 50 \cdot 5 = 7500 \\ M_1 \cdot (M_2 \cdot M_3) & cost = r_2 \cdot c_3 \cdot c_2 + r_1 \cdot c_3 \cdot c_1 = 100 \cdot 50 \cdot 5 + 10 \cdot 50 \cdot 100 = 75000 \end{array}$$

❖ Thus, computing the product according to the first parenthesization is **10 times faster**

## Parenthesization

- ❖ When we have  $n$  matrices, we need to resolve all ambiguities in how the matrices are multiplied together

A product of matrices is fully parenthesized if it is either a single matrix or the product of two fully parenthesized matrix products, surrounded by parenthesis

- ❖ We need to **parenthesized** the product
  - Matrix multiplication is **associative**, and so all parenthesizations yield the same product
  - As we have seen the **cost** in terms of the number of scalar multiplications is not always the same

# Complexity

- ❖ Given the product  $n$  matrices
  - How many parenthesisations are possible?
- ❖ We can prove that given
  - The number of possible parenthesisations is  $\Omega(2^n)$  thus exponential in  $n$
  - Exhaustively checking (brute-force) all possible parenthesisations does not yield an efficient algorithm

$$M = M_1 \cdot M_2 \cdot M_3 \cdot M_4$$

$$\begin{aligned} & (((M_1 \cdot M_2) \cdot M_3) \cdot M_4) \\ & ((M_1 \cdot M_2) \cdot (M_3 \cdot M_4)) \\ & ((M_1 \cdot (M_2 \cdot M_3)) \cdot M_4) \\ & (M_1 \cdot ((M_2 \cdot M_3) \cdot M_4)) \\ & (M_1 \cdot (M_2 \cdot (M_3 \cdot M_4))) \end{aligned}$$

## Applying dynamic programming

### ❖ The structure of an optimal parenthesization

- Let us suppose we need to optimize

$$M_i \cdot M_{i+1} \cdot M_{i+2} \cdot \dots \cdot M_j$$

- We can suppose to split the product for some value of  $k$ , i.e.,

$$(M_i \cdot \dots \cdot M_K) \cdot (M_{K+1} \cdot \dots \cdot M_j)$$

- If this product is optimum, the 2 subproducts must be optimum

# Applying dynamic programming

## ❖ A recursive solution

➤ Let us call  $m[i, j]$  the minimum cost to compute

$$M_i \cdot M_{i+1} \cdot M_{i+2} \cdot \dots \cdot M_j$$

$$(M_i \cdot \dots \cdot M_K) \cdot (M_{K+1} \cdot \dots \cdot M_j)$$

➤ We have that

$$m[i, j] = \begin{cases} 0 & \text{if } i = j \\ \min_{i \leq k < j} \{m[i, k] + m[k + 1, j] + r_i \cdot c_k \cdot c_j\} & \text{if } i < j \end{cases}$$

➤ We define  $s[i, j]$  the value of  $k$  at which we split the product in optimal parenthesization

## Applying dynamic programming

### ❖ Computing the optimal costs

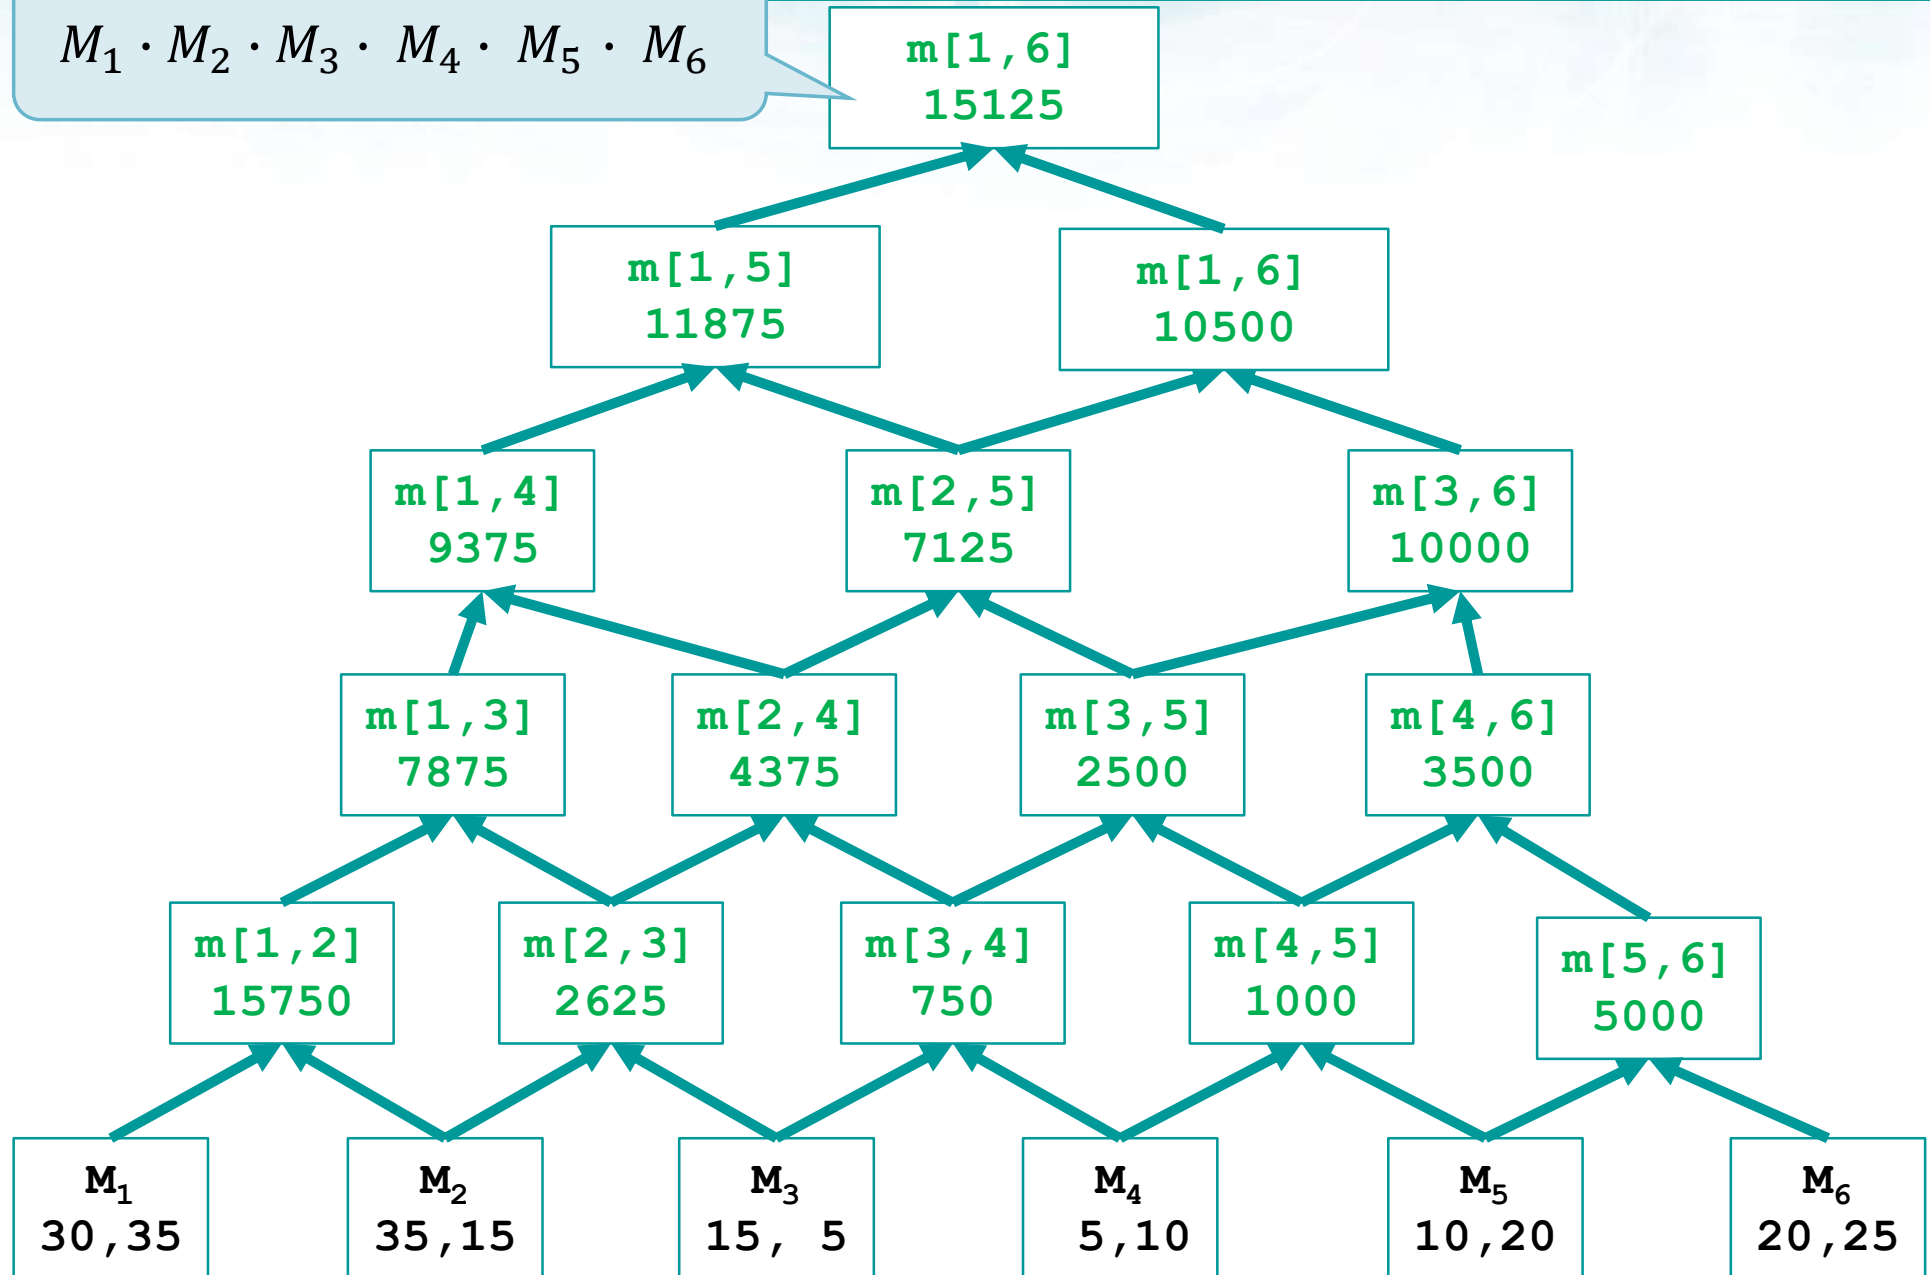

- Instead of computing the solution to the previous recurrence recursively, we compute the optimal cost by using a tabular, bottom-up approach
- The procedure uses an auxiliary table  $m[1 \cdots n, 1 \cdots n]$  to storing the cost to compute the product and another auxiliary table  $s[1 \cdots n - 1, 2 \cdots n]$  to identify the value of  $k$  for such a cost

## Applying dynamic programming

- ❖ In order to implement the bottom-up approach, we must determine which entries of the table we refer to when computing  $m[i, j]$ 
  - The previous equation shows that the cost of computing a matrix-chain product depends only on the costs of computing matrix-chain products of fewer matrices
- ❖ Thus, the algorithm should fill in the table  $m$  in a manner that corresponds to solving the parenthesization problem on matrix chains of increasing length

# Example

$$M_1 \cdot M_2 \cdot M_3 \cdot M_4 \cdot M_5 \cdot M_6$$

## Example

$m[1][2]$	=	0+	0+	30x	35x	15=	15750	MIN
$m[2][3]$	=	0+	0+	35x	15x	5=	2625	MIN
$m[3][4]$	=	0+	0+	15x	5x	10=	750	MIN
$m[4][5]$	=	0+	0+	5x	10x	20=	1000	MIN
$m[5][6]$	=	0+	0+	10x	20x	25=	5000	MIN
$m[1][3]$	=	0+	2625+	30x	35x	5=	7875	MIN
		15750+	0+	30x	15x	5=	18000	
$m[2][4]$	=	0+	750+	35x	15x	10=	6000	MIN
		2625+	0+	35x	5x	10=	4375	MIN

## Example

m[3][5] =	0+	1000+	15x	5x	20=	2500	MIN
	750+	0+	15x	10x	20=	3750	
m[4][6] =	0+	5000+	5x	10x	25=	6250	MIN
	1000+	0+	5x	20x	25=	3500	MIN
m[1][4] =	0+	4375+	30x	35x	10=	14875	MIN
	15750+	750+	30x	15x	10=	21000	
	7875+	0+	30x	5x	10=	9375	MIN
m[2][5] =	0+	2500+	35x	15x	20=	13000	MIN
	2625+	1000+	35x	5x	20=	7125	MIN
	4375+	0+	35x	10x	20=	11375	
m[3][6] =	0+	3500+	15x	5x	25=	5375	MIN
	750+	5000+	15x	10x	25=	9500	
	2500+	0+	15x	20x	25=	10000	

## Example

<b>m[1][5] =</b>	0+	7125+	30x	35x	20=	28125	
	15750+	2500+	30x	15x	20=	27250	
	7875+	1000+	30x	5x	20=	11875	<b>MIN</b>
	9375+	0+	30x	10x	20=	15375	

<b>m[2][6] =</b>	0+	5375+	35x	15x	25=	18500	
	2625+	3500+	35x	5x	25=	10500	<b>MIN</b>
	4375+	5000+	35x	10x	25=	18125	
	7125+	0+	35x	20x	25=	24625	

<b>m[1][6] =</b>	0+	10500+	30x	35x	25=	36750	
	15750+	5375+	30x	15x	25=	32375	
	7875+	3500+	30x	5x	25=	15125	<b>MIN</b>
	9375+	5000+	30x	10x	25=	21875	
	11875+	0+	30x	20x	25=	26875	

# Example

# Implementation

```
p = readSizes (argv[1], &n);
m = (int **)util_matrix_alloc(n+1, n+1, sizeof(int));
for (i=0; i<=n; i++) {
    for (j=0; j<=n; j++) {
        m[i][j] = ((i==j) ? 0 : INT_MAX);
    }
}
best = matrixChainOrder (p, m, n);
matrixChainPrint (m, 1, n);
```

# Implementation

```
int *readSizes(char *filename, int *num) {
    int i, n, *p;
    FILE *fp;

    fp = util_fopen(filename, "r");
    fscanf(fp, "%d", &n);
    p = (int *)util_malloc((n+1)*sizeof(int));
    for (i=0; i<n; i++) {
        fscanf(fp, "%dx%d", &p[i], &p[i+1]);
    }
    fclose(fp);
    *num = n;
    return p;
}
```

# Implementation

```
int matrixChainOrder(int *p, int **m, int n) {
    int i, j, k, l, cost;
    for (l=2; l<=n; l++) {
        for (i=1; i<=n-l+1; i++) {
            j = i+l-1;
            for (k=i; k<=j-1; k++) {
                cost = m[i][k] + m[k+1][j] + p[i-1]*p[k]*p[j];
                if (cost < m[i][j]) {
                    m[i][j] = cost;
                    m[j][i] = k;
                }
            }
        }
    }
    return m[1][n];
}
```

# Implementation

```
void matrixChainPrint (int **m, int i, int j) {
    int k;

    if (i == j) {
        printf("A%d", i);
        return;
    }

    k = m[j][i];
    printf("(");
    matrixChainPrint(m, i, k);
    printf(" * ");
    matrixChainPrint(m, k+1, j);
    printf(")");
}
```

## Longest common subsequence

- ❖ A subsequence of a given sequence is just the given sequence with zero or more elements left out
  - For example, {A, E, F, H} is a subsequence of {A, B, C, D, E, F, G, H}
- ❖ Given two sequences X and Y , we say that a sequence Z is a common subsequence of X and Y if Z is a subsequence of both X and Y
  - For example, {D, F, H} is a common subsequence of {A, B, C, D, E, F, G, H} and {D, F, G, H, I, L, M, N}

## Longest common subsequence

- ❖ In the longest-common-subsequence (LCS) problem, we are given two sequences

$$X = \{x_1, x_2, x_3, \dots, x_m\}$$
$$Y = \{y_1, y_2, y_3, \dots, y_n\}$$

- We wish to find a maximum-length common subsequence of  $X$  and  $Y$

## Brute-force solution

- ❖ In a brute-force approach to solving the LCS problem, we would enumerate all subsequences of  $X$  and check each subsequence to see whether it is also a subsequence of  $Y$ , keeping track of the longest subsequence we find
- ❖ Each subsequence of  $X$  corresponds to a subset of the indices  $\{1, 2, \dots, m\}$  of  $X$
- ❖ Because  $X$  has  $(2 \cdot m)$  subsequences, this approach requires exponential time, making it impractical for long sequences

# Implementation

... given strX and strY ...

```
lX = strlen(strX)+1;
```

```
lY= strlen(strY)+1;
```

```
b = (int **)2D_malloc(lX, lY, sizeof(int));
```

```
c = (int **)2D_malloc(lX, lY, sizeof(int));
```

```
l = lcsLength(strX, strY, b, c);
```

```
printf("LCS length: %d\n", length);
```

```
printf("LCS: ");
```

```
lcsPrint(strX, b, c, lengthX-1, lengthY-1);
```

```
printf("\n");
```

```
2D_dispose((void ***)b, lX, lY, NULL);
```

```
2D_dispose((void ***)c, lX, lY, NULL);
```

# Implementation

```
int lcsLength (
    char *strX, char *strY, int **b, int **c) {
    int i, j, m = strlen(strX), n = strlen(strY);
    for (i=1; i<=m; i++) {
        for (j=1; j<=n; j++) {
            if (strX[i-1] == strY[j-1]) {
                c[i][j] = c[i-1][j-1] + 1; b[i][j] = DIAG;
            } else {
                if (c[i-1][j] >= c[i][j-1]) {
                    c[i][j] = c[i-1][j]; b[i][j] = UP;
                } else {
                    c[i][j] = c[i][j-1]; b[i][j] = LEFT;
                }
            }
        }
    }
    return c[m][n];
}
```

# Implementation

```
void lcsPrint (
    char *strX, int **b, int **c, int i, int j) {
    if (i!=0 && j!=0) {
        if (b[i][j] == DIAG) {
            lcsPrint(strX, b, c, i-1, j-1);
            printf("%c", strX[i-1]);
        } else {
            if (b[i][j] == UP) {
                lcsPrint(strX, b, c, i-1, j);
            } else {
                lcsPrint(strX, b, c, i, j-1);
            }
        }
    }
}
```

# Example

❖ Find the LCS between the two strings

$X = \{A, B, C, B, D, A, B\}$

$Y = \{A, D, C, A, B, A\}$

recursive solution

```
int LCS(int *A, int *B, int i, int j){
    if (A[i]=='\0' || B[j]=='\0')
        return 0;
    else if (A[i]==B[j])
        return 1+LCS(A, B, i+1, j+1);
    else
        return max(LCS(i+1,j),LCS(i,j+1));
}
```

	j	0	1	2	3	4	5	6
i		yi	B	D	C	A	B	A
0	xi	0	0	0	0	0	0	0
1	A	0	↑0	↑0	↑0	1	←1	1
2	B	0	1	←1	←1	↑1	2	←2
3	C	0	↑1	↑1	2	←2	↑2	↑2
4	B	0	1	↑1	↑2	↑2	↑3	↑3
5	D	0	↑1	2	↑2	↑2	↑3	↑3
6	A	0	↑1	↑2	↑2	3	↑3	4
7	B	0	1	↑2	↑2	↑3	4	↑4
